## 1 Estimation accuracy for more general randomized SVD

We generalize from random normal test matrices to arbitrary test matrices. We can guarantee the convergence of estimators under the certain conditions in the next theorem.

Theorem 1. Let  $A = \mathcal{C} \times_1 M^{(1)} \times_2 \cdots \times_N M^{(N)}$  be a signal tensor, where  $\mathcal{C} \in \mathbb{R}^{r_1 \times \cdots \times r_N}$  is a core tensor and  $M^{(i)}$  is an orthonormal matrix in  $\mathbb{R}^{d_i \times r_i}$  for all  $i \in [N]$ . Let  $\mathcal{D} = A + \mathcal{E}$  be a noisy tensor with a noise tensor  $\mathcal{E}$  with i.i.d. entries from  $N(0, \sigma^2)$ . Suppose,  $(\hat{\mathcal{C}}, \hat{M}^{(1)}, \cdots, \hat{M}^{(N)})$  is obtained from the randomized algorithms with test matrices  $\Omega^{(i)}$  for  $i \in [N]$ . If  $s_{min}(C_{(i)})\sqrt{\mathbb{1}_{r_i}^T(\Omega^{(i)})^TP^{(i)}(P^{(i)})^T\Omega^{(i)}\mathbb{1}_{r_i}} >> \sigma\sqrt{r_i \max(d_i, \frac{\prod_{j\neq i}d_j}{d_i})}\|\Omega^{(i)}\|_{\sigma}$  as  $d_1, \cdots, d_N \to \infty$ , where  $s_{min}(C_{(i)})$  is the smallest singular value of  $C_{(i)}$ ,  $P^{(i)} = [(M^{(N)} \otimes \cdots \otimes M^{(i+1)} \otimes M^{(i-1)} \otimes \cdots \otimes M^{(1)})V_{r_i}^{(i)}]$  and  $V_{r_i}^{(i)}$  is the matrix of the r largest left singular vectors of  $C_{(i)}$ . Then, the following holds true.

$$\cos \theta(M^{(i)}, \hat{M}^{(i)}) \to 1$$
 in probability for  $i \in [3]$ .

$$\|\mathcal{A} - \hat{\mathcal{A}}\|_F \to 0$$
 in probability.

where 
$$\hat{\mathcal{A}} = \hat{\mathcal{C}} \times_1 \hat{M}^{(1)} \times_2 \cdots \times_N \hat{M}^{(N)}$$
.

*Proof.* It suffices to show when i = 1. Notice,

$$A_{(1)} = M^{(1)} (\mathcal{C} \times_2 M^{(2)} \times_3 \dots \times_N M^{(N)})_{(1)}$$
  
=  $M^{(1)} C_{(1)} (M^{(N)} \otimes \dots \otimes M^{(2)})^T$ .

Define  $B = (M^{(N)} \otimes \cdots \otimes M^{(2)})$ , the randomized algorithms generates a test matrix  $\Omega^{(1)}$  and captures the image space of unfolded matrix  $A_{(1)}$ . Having this procedure in mind, we obtain,

$$A_{(1)}\Omega^{(1)} = M^{(1)}C_{(1)}(M^{(N)} \otimes \cdots \otimes M^{(2)})^T \Omega^{(1)}$$
$$= M^{(1)}C_{(1)}B^T \Omega^{(1)}.$$

However, since the input is  $\mathcal{D} = \mathcal{A} + \mathcal{E}$ , we have the image space of  $A_{(1)} + E_{(1)}$  instead of  $A_{(1)}$ . Therefore, the estimator  $\hat{M}^{(1)}$  is obtained from the following equality.

$$(A_{(1)} + E_{(1)})\Omega^{(1)} = M^{(1)}C_{(1)}B^T\Omega^{(1)} + E_{(1)}\Omega^{(1)}$$
  
=  $\hat{M}^{(1)}R$  (QR decomposition).

From the relationship that  $\operatorname{span}(A_{(1)}\Omega^{(1)}) \subset \operatorname{span}(M^{(1)})$  and  $\operatorname{span}(A_{(1)}\Omega^{(1)} + E_{(1)}\Omega^{(1)}) = \operatorname{span}(\hat{M}^{(1)})$ , we have the following.

$$\cos \theta(M^{(1)}, \hat{M^{(1)}}) = \max_{u \in \text{span}(M^{(1)}), v \in \text{span}(\hat{M}^{(1)})} \cos(u, v) 
\geq \max_{u \in \text{span}(A_{(1)}\Omega^{(1)}), v \in \text{span}((A_{(1)} + E_{(1)})\Omega^{(1)})} \cos(u, v) 
= \max_{x \in R^{r_1}, y \in R^{r_1}, ||x||_2 = ||y||_2 = 1} \cos(A_{(1)}\Omega^{(1)}x, (A_{(1)} + E_{(1)})\Omega^{(1)}y).$$
(1)

The first argument in the theorem holds true by (1) if

$$\max_{x \in R^{r_1}, y \in R^{r_1}, ||x||_2 = ||y||_2 = 1} \cos(A_{(1)}\Omega^{(1)}x, (A_{(1)} + E_{(1)})\Omega^{(1)}y) \to 1.$$
(2)

Also (2) holds true, if

$$\cot(A_{(1)}\Omega^{(1)}x, (A_{(1)} + E_{(1)})\Omega^{(1)}y) \to \infty \text{ for some } x, y \text{ such that } ||x|| = ||y|| = 1.$$
 (3)

So the main proof of this theorem is to show (3). We prove (3) by the following inequality.

$$\cot(A_{(1)}\Omega^{(1)}x, (A_{(1)} + E_{(1)})\Omega^{(1)}y) \ge \frac{\|A_{(1)}\Omega^{(1)}x\|_2}{\|E_{(1)}\Omega^{(1)}y\|_2} \ge \frac{s_{min}(C_{(1)})\sqrt{\mathbb{1}_{r_1}^T(\Omega^{(1)})^T P^{(1)}(P^{(1)})^T \Omega^{(1)}\mathbb{1}_{r_1}}}{\sqrt{r_1}\|E\|_F\|\Omega^{(1)}\|_{\sigma}}.$$
(4)

for some x and y.

To get the numerator part in (4),

$$||A_{(1)}\Omega^{(1)}x||_{2} = ||M^{(1)}C_{(1)}B^{T}\Omega^{(1)}x||_{2}$$

$$\stackrel{(i)}{=} ||C_{(1)}B^{T}\Omega^{(1)}x||_{2}$$

$$\stackrel{(ii)}{=} ||U^{(1)}\Sigma^{(1)}(V^{(1)})^{T}B^{T}\Omega^{(1)}x||_{2}$$

$$= ||\Sigma^{(1)}(V_{r_{1}}^{(1)})^{T}B^{T}\Omega^{(1)}x||_{2}$$

$$\geq s_{\min}(C_{(1)})||(V_{r_{1}}^{(1)})^{T}B^{T}\Omega^{(1)}x||_{2}$$

$$= s_{\min}(C_{(1)})||(P^{(1)})^{T}\Omega^{(1)}x||_{2}$$

$$\stackrel{(iii)}{=} s_{\min}(C_{(1)})\frac{1}{\sqrt{r_{1}}}||(P^{(1)})^{T}\Omega^{(1)}\mathbb{1}_{r_{1}}||_{2}$$

$$= \frac{s_{\min}(C_{(1)})\sqrt{\mathbb{1}_{r_{1}}^{T}(\Omega^{(1)})^{T}P^{(1)}(P^{(1)})^{T}\Omega^{(1)}\mathbb{1}_{r_{1}}}}{\sqrt{r_{1}}}$$

(i) is from the orthonormality of  $M^{(1)}$ . Singular value decomposition of  $C_{(1)}$  is used in (ii). Notice, In (iii), we put  $x = \mathbb{1}_{r_1}/\sqrt{r_1}$ . Therefore, we get the numerator part. For the denominator of (4), we knows

$$||E||_F \simeq (2 + o(1))\sigma\sqrt{\max(d_1, d_2 \cdots d_N)}.$$

Also, notice that

$$\|\Omega y\|_2 \leq \|\Omega\|_{\sigma}$$
.

Therefore, we get (4). The last argument that  $\|\mathcal{A} - \hat{\mathcal{A}}\| \to 0$  is derived directly from Theorem 2 and Theorem 3 in the 7th meeting note.

When all entries of the test matrices are i.i.d. from N(0,1), we have the following corollary.

Corollary 1. Let  $\mathcal{A} = \mathcal{C} \times_1 M^{(1)} \times_2 M^{(2)} \times_3 M^{(3)}$  be a signal tensor, where  $\mathcal{C} \in \mathbb{R}^{r_1 \times r_2 \times r_3}$  is a core tensor and  $M^{(1)}, M^{(2)}, M^{(3)}$  are orthonormal matrices in  $\mathbb{R}^{d_1 \times r_1}, \mathbb{R}^{d_2 \times r_2}, \mathbb{R}^{d_3 \times r_3}$  respectively. Suppose we use standard normal random matrices as test matrices in Theorem 1. If  $s_{min}(C_{(i)}) >> \sigma \sqrt{\max(d_i, \frac{d_1 d_2 d_3}{d_i}) \frac{d_1 d_2 d_3}{d_i r_i}}$  as  $d_1, d_2, d_3 \to \infty$ , where  $s_{min}(C_{(i)})$  is the smallest singular value of  $C_{(i)}$ . Then, the following holds true.

$$\cos \theta(M^{(i)}, \hat{M}^{(i)}) \to 1$$
 in probability for  $i \in [3]$ .

$$\|\mathcal{A} - \hat{\mathcal{A}}\|_F \to 0$$
 in probability.

*Proof.* It is enough to show that the condition in Theorem 1 implies the condition in the Corollary 1. We will show this argument when i = 1 with fixed  $\Omega^{(1)}$  replaced by a standard normal random matrix. First, let us check

$$\sqrt{\mathbb{1}_{r_1}^T(\Omega^{(1)})^T P^{(1)}(P^{(1)})^T \Omega^{(1)} \mathbb{1}_{r_1}}.$$
 (5)

where  $\Omega^{(1)}$  is a standard normal random matrix. Notice,

$$(P^{(1)})^T \Omega^{(1)} \mathbb{1}_{r_1} \sim (P^{(1)})^T N_{r_1} (0, r_1 I_{r_1}) \stackrel{\mathrm{d}}{=} N_{r_1} (0, r_1 (P^{(1)})^T P^{(1)}) = N_{r_1} (0, r_1 I_{r_1}).$$

Because  $(P^{(1)})^T P^{(1)} = I_{r_1}$  by the definition of  $P^{(1)}$ . We get the following distribution for (5).

$$\sqrt{\mathbb{1}_{r_1}^T(\Omega^{(1)})^T P^{(1)}(P^{(1)})^T \Omega^{(1)} \mathbb{1}_{r_1}} \stackrel{\mathrm{d}}{=} \sqrt{N_{r_1}(0, r_1 I_{r_1})^T N_{r_1}(0, r_1 I_{r_1})} \stackrel{\mathrm{d}}{=} \sqrt{r_1 \chi_{r_1}^2}.$$
 (6)

Secondly, we have

$$\|\Omega^{(1)}\|_{\sigma} \ge \|\Omega^{(1)}y\|_{2} \quad \text{where } y \in \mathbb{R}^{r_{1}} \text{ such that } \|y\|_{2} = 1$$

$$\stackrel{d}{=} \sqrt{N_{d_{2}d_{3}}(0, I_{d_{2}d_{3}})^{T} N_{d_{2}d_{3}}(0, I_{d_{2}d_{3}})}$$

$$\stackrel{d}{=} \sqrt{\chi_{d_{2}d_{3}}^{2}}$$

$$\approx (1 + o(1))\sqrt{d_{2}d_{3}}.$$

Therefore, the condition in Theorem 1 can be rewritten as,

$$s_{\min}(C_{(1)})\sqrt{\chi_{r_1}^2} >> \sigma\sqrt{\max(d_1, d_2d_3)d_2d_3}.$$
 (7)

By the following inequality, we have the condition of this corollary from (7). (7) implies the left side of the following equation converges to 1.

$$P(s_{\min}(C_{(1)})\sqrt{\chi_{r_1}^2} > \sigma\sqrt{\max(d_1, d_2d_3)d_2d_3}) = P(\chi_{r_1}^2 \ge \frac{\sigma^2d_2d_3\max(d_1, d_2d_3)}{s_{\min}(C_{(1)})^2})$$

$$\stackrel{(i)}{\le} 1 - \left(\lambda e^{1-\lambda}\right)^{\frac{r_1}{2}}.$$

In (i), we defined  $\lambda \stackrel{def}{=} \frac{\sigma^2 d_2 d_3 \max(d_1, d_2 d_3)}{r_1 s_{\min}(C_{(1)})^2}$  and used Chernoff bounds,

$$P(\chi_r^2 \ge t) \le 1 - \left(\frac{t}{r}e^{1-\frac{t}{r}}\right)^{\frac{r}{2}}$$
 for any  $t \ge 0$ .

Therefore,  $\lambda$  should converge to 0 when (7) holds. Now we have the condition of the corollary true.

## 2 Extended angle simulation for an arbitrary rank

This simulation investigates the accuracy of estimators in terms of angles and MSE for an arbitrary rank. We consider an order-3 dimension (20, 20, 20) signal tensor X. We assume X has Tucker decomposition as  $X = \mathcal{C} \otimes_1 B_1 \otimes_2 B_2 \otimes_3 B_3$ , where  $B_i \in \mathbb{R}^{20 \times 3}$  for all i. and  $\mathcal{C} \in \mathbb{R}^{3 \times 3 \times 3}$  a core tensor. All entries of  $\mathcal{C}, B_1, B_2, B_3$  are i.i.d. drawn from N(0,1). We vary the noise level  $\sigma \in \{0.01, 0.02, \cdots 0.49, 0.5\}$ . We use target rank 3 and estimate the signal matrices according to each algorithms. We compare the principal angles between the true signal matrices and estimators. Figure 1 shows that Method 3 outperforms the other methods in MSE. However, our simulation does not show consistent result for the principal angles. I think we need to find a good reason for this phenomena.

## 3 Improved ordinal tensors algorithm

First, I constructed stochastic gradient descent(SGD) algorithm for updating the core tensor. However, there were some problems to implement SGD method. First, I used various batch sizes from B=100 to B=1000. But this algorithm had more than 100 the number of iterations in all batch sizes. Secondly, I picked the tolerance size as  $10^-4$ . this algorithm reached to this tolerance size fast but had the smaller likelihood value that the value with the true parameter. This means it did not get to the optimal point but had small improvement on each update. In addition, I found that it also has variation issues, which is inevitable. There were some cases that this algorithm worked quite well with moderate iteration numbers and time. However, it sometimes performed poorly with large iteration numbers and bad outputs. Instead of using stochastic gradient method, I constructed the algorithm which calculate hessian in each update for the core tensor. This hessian function reduced iteration

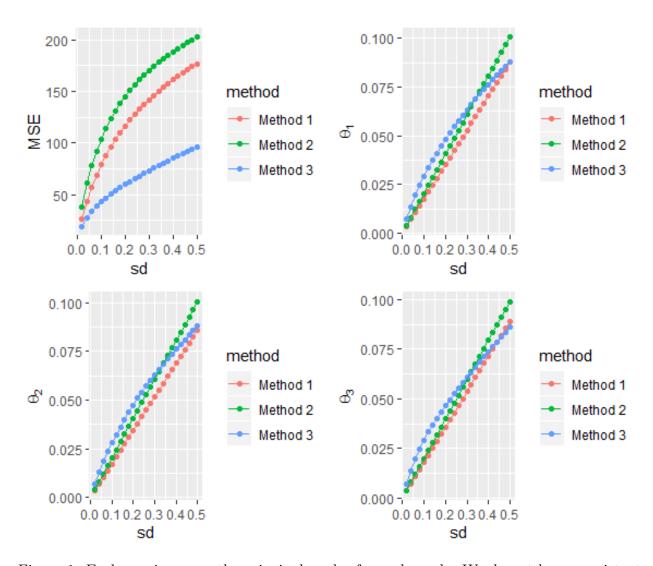

Figure 1: Each y axis means the principal angles for each mode. We do not have consistent simulation results: Method 3 has the best performance in MSE but Method 1 has better for the principal angles thought they have minor different values

time dramatically for updating the core tensor. Also, it converged with the less the number of iterations than the previous algorithm. All output had the greater likelihood value than the value with the true parameters.

#### 3.1 Simulation for ordinal tensors

I performed the simulations having the same setting as in section 3.2 in the 7-th note. I summarized the output as follows.

1. When 
$$d = 20$$
 and  $r = 3$  with  $\max(\Theta_{\text{True}}) = 5.78633$  and  $\omega = (-0.2, 0.2)$ .  
We have  $L(\Theta_{\text{True}}) = 6459.568$  and  $L(\Theta_0) = 7414.672$ .

	(with $\omega$ information)	(Without $\omega$ inforantion)
$L(\hat{\Theta})$	6373.461	6373.191
Computation time	51 sec	$52  \sec$

When we implement algorithm without  $\omega$  information, we have an estimate  $\hat{\omega} = (-1.8011, 0.2513)$ 

2. When 
$$d = 30$$
 and  $r = 3$  with  $\max(\Theta_{\text{True}}) = 6.8348$  and  $\omega = (-0.2, 0.2)$ .  
We have  $L(\Theta_{\text{True}}) = 21895.92$  and  $L(\Theta_0) = 24917.37$ .

	(with $\omega$ information)	(Without $\omega$ inforamtion)
$L(\hat{\Theta})$	21761.86	21761.92
Computation time	$432  \sec$	385.56  sec

When we implement algorithm without  $\omega$  information, we have an estimate  $\hat{\omega} = (-0.221403, 0.1868)$ 

The following is the scatter plot between true parameters and estimators.

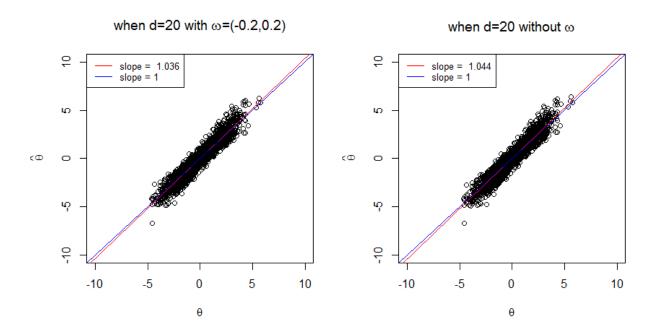

Figure 2: When d = 20. Red lines are slopes of ordinary least square estimators. Blue lines are line of y = x.

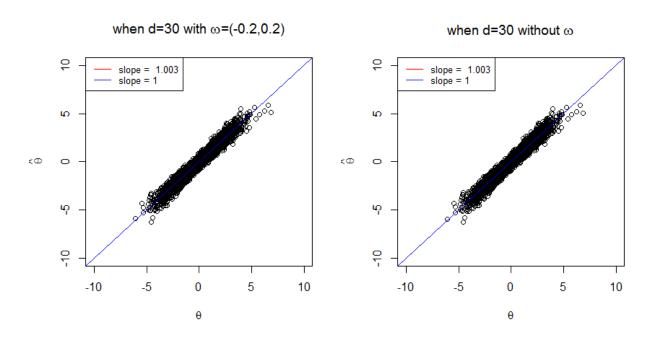

Figure 3: When d=30. Red lines are slopes of ordinary least square estimators. Blue lines are line of y=x.

We can check that our estimators has a tendency to overestimate the true parameters.

The reason we had the opposite tendency in the 7th note is that I made mistake to calculate the slope of each scatter plot. I put  $\Theta_{\text{True}}$  into response variables and  $\hat{\Theta}$  into explanatory variables, which is the opposite direction from what I wanted to calculate. I checked we have the same overestimation tendency from the previous algorithm too if I calculate the slope in the right way. Another thing to notice is the new algorithm performs better when d=20 compared to the previous one. I think Hessian function played major rule to calculate the optimizer with more accuracy and less computation time.

## 4 Algorithms

#### 4.1 Extended angle simulation

```
library(rTensor)
2 library(pracma)
3 B_1 = matrix(rnorm(20*3), nrow = 20)
_{4} B_{2} = matrix(rnorm(20*3), nrow = 20)
5 B_3 = matrix(rnorm(20*3), nrow = 20)
_{6} C = as.tensor(array(rnorm(3^3),dim = c(3,3,3)))
7 X = ttm(ttm(ttm(C, B_1, 1), B_2, 2), B_3, 3)
